

OMNIX-RTE-001 v1.1.0

Reviewer Distribution Emails

Runtime Treasury Execution Trace | USD 50,000,000 | SWIFT MT202 / XRPL

CONTEXT

The TA-14 public-material review (May 27, 2026) identified route-complete admissibility proof as the main evidence threshold for OMNIX.

OMNIX-RTE-001 v1.1.0 was built as a direct response to that finding. It covers all 8 steps of the Suggested Demonstration Route from the TA-14 review: source state through outcome, twice -- one path producing hard refusal (HALT), one producing bounded execution (settlement released).

After internal adversarial testing (15 attacks, 4 bypasses found in v1.0.0), all 4 bypasses were remediated. The current package passes 111 of 111 checks, 0 failures.

ENGLISH VERSION

Gregory,

Thank you for the TA-14 public-material review dated May 27. The central finding was clear: route-complete admissibility proof was the next evidence threshold.

Attached is OMNIX-RTE-001 v1.1.0 -- a runtime treasury execution trace built directly against your Suggested Demonstration Route.

It covers all 8 steps: source state through outcome, twice -- one path producing hard refusal (HALT, settlement blocked), one producing bounded execution (USD 50,000,000 released via SWIFT MT202 / XRPL). Every artifact is PQC-signed (ML-DSA-65, FIPS 204) and verifiable offline without access to OMNIX infrastructure.

The package includes a standalone verifier (single Python file, stdlib + optional pqc). After an internal adversarial review that found 4 bypasses in v1.0.0, all 4 were remediated. The current version passes 111 of 111 checks, 0 failures.

To verify:

```
unzip OMNIX-RTE-001-REVIEWER_20260528_085038.zip
cd OMNIX-RTE-001-REVIEWER
python verify.py
```

I am interested in whether this satisfies the route-complete admissibility threshold from a TA-14 standpoint, and specifically whether you find anything the verifier should catch that it does not.

TRADUCCION AL ESPANOL

Gregory,

Gracias por la revision TA-14 del 27 de mayo. El hallazgo central fue claro: la prueba de admisibilidad ruta-completa era el proximo umbral de evidencia.

Adjunto el OMNIX-RTE-001 v1.1.0 -- un runtime treasury execution trace construido directamente contra tu Suggested Demonstration Route.

Cubre los 8 pasos: desde source state hasta outcome, dos veces -- un path produciendo hard refusal (HALT, settlement bloqueado), y uno produciendo ejecucion acotada (USD 50,000,000 liberados via SWIFT MT202 / XRPL). Cada artefacto esta firmado PQC (ML-DSA-65, FIPS 204) y es verificable offline sin acceso a la infraestructura de OMNIX.

El package incluye un verifier standalone (un solo archivo Python, stdlib + pqc opcional). Despues de una revision adversarial interna que encontro 4 bypasses en v1.0.0, todos fueron remediados. La version actual pasa 111 de 111 checks, 0 fallos.

Para verificar:

```
unzip OMNIX-RTE-001-REVIEWER_20260528_085038.zip
cd OMNIX-RTE-001-REVIEWER
python verify.py
```

Me interesa saber si esto satisface el umbral de admisibilidad ruta-completa desde la perspectiva TA-14, y especificamente si encuentras algo que el verifier deberia detectar y no detecta.

ENGLISH VERSION

Anamulla,

Attached is the OMNIX-RTE-001 v1.1.0 reviewer package -- our first complete dual-path execution trace for a USD 50,000,000 autonomous treasury scenario.

Short version: a third-party TA-14 review identified route-complete proof as the main gap in our public materials. This package closes that gap directly. It shows the system blocking an inadmissible execution and admitting a compliant one -- with every decision cryptographically signed and verifiable offline by anyone with a Python interpreter.

The package survived internal adversarial testing (15 attacks, 4 bypasses found and closed). It includes a standalone verifier, 15-page institutional PDF, and formal remediation documentation.

To verify:

```
unzip OMNIX-RTE-001-REVIEWER_20260528_085038.zip
cd OMNIX-RTE-001-REVIEWER
python verify.py
```

I am sending this to a small number of external reviewers. Let me know your read.

TRADUCCION AL ESPANOL

Anamulla,

Adjunto el OMNIX-RTE-001 v1.1.0 reviewer package -- nuestro primer execution trace dual-path completo para un escenario de tesoreria autonoma de USD 50,000,000.

En resumen: una revision TA-14 externa identifico la prueba ruta-completa como el principal gap en nuestros materiales publicos. Este package cierra ese gap directamente. Muestra el sistema bloqueando una ejecucion inadmissible y admitiendo una conforme -- con cada decision firmada criptograficamente y verificable offline por cualquier persona con un interprete Python.

El package sobrevivio pruebas adversariales internas (15 ataques, 4 bypasses encontrados y cerrados). Incluye un verifier standalone, PDF institucional de 15 paginas, y

documentacion formal de remediacion.

Para verificar:

```
unzip OMNIX-RTE-001-REVIEWER_20260528_085038.zip
cd OMNIX-RTE-001-REVIEWER
python verify.py
```

Estoy enviando esto a un numero pequeno de revisores externos. Cuéntame que piensas.

Harold Nunes
